

Introduction to Bulk RNAseq data analysis

Quantification of Gene Expression with Salmon

Exercise 1 - Create Salmon index

1. Create concatenated transcriptome/genome reference file

```
cat references/Mus_musculus.GRCm38.cdna.chr14.fa.gz \
    references/Mus_musculus.GRCm38.dna_sm.chr14.fa.gz \
    > references/gentrome.chr14.fa.gz
```

2. Create decoy sequence list from the genomic fasta

```
echo "14" > references/decoys.txt
```

3. Use `salmon index` to create the index. You will need to provide three pieces of information:
 - the **Transcript fasta file** - `references/gentrome.chr14.fa.gz`
 - the **decoys** - `references/decoys.txt`
 - the **salmon index** - a directory to write the index to, use `references/salmon_index_chr14`

Also add `-p 7` to the command to instruct salmon to use 7 threads/cores. To find the flags for the other three pieces of information use:

```
salmon index --help
```

Version Info: This is the most recent version of salmon.

Index

=====

Creates a salmon index.

Command Line Options:

<code>-v [--version]</code>	print version string
<code>-h [--help]</code>	produce help message
<code>-t [--transcripts] arg</code>	Transcript fasta file.
<code>-k [--kmerLen] arg (=31)</code>	The size of k-mers that should be used for the quasi index.
<code>-i [--index] arg</code>	salmon index.
<code>--gencode</code>	This flag will expect the input transcript
<code>...</code>	
<code>...</code>	
<code>...</code>	
<code>-d [--decoys] arg</code>	Treat these sequences ids from the reference as the decoys that may have sequence homologous to some known transcript. for example in case of the genome, provide a list of chromosome name --- one per line

```
salmon index \
    -t references/gentrome.chr14.fa.gz \
    -d references/decoys.txt \
```

```
-p 7 \  
-i references/salmon_index_chr14
```

Exercise 2 - Quantify with Salmon

1. Make directory called `salmon_output`

```
mkdir salmon_output
```

2. Use `salmon quant` to quantify the gene expression from the raw fastq. To see all the options run `salmon quant --help-reads`. There are lot of possible parameters, we will need to provide the following:
 - **salmon index** - *references/salmon_index*
 - **-l A** - Salmon needs to use some information about the library preparation, we could explicitly give this, but it is easy enough for Salmon to Automatically infer this from the data.
 - **File containing the #1 mates** - *fastq/SRR7657883.subset_2M.sra_1.fastq.gz*
 - **File containing the #2 mates** - *fastq/SRR7657883.subset_2M.sra_2.fastq.gz*
 - **--writeMappingssalmon_output/SRR7657883.salmon.sam** - Instructs Salmon to output the read alignments in SAM format to the file *salmon_output/SRR7657883.salmon.sam*.
 - **Output quantification directory** - *salmon_output/SRR7657883*
 - **--gcBias** - salmon can optionally correct for GC content bias, it is recommended to always use this
 - **The number of threads to use** - 7

```
salmon quant \  
-p 7 \  
-i references/salmon_index \  
--gcBias \  
-l A \  
-1 fastq/SRR7657883.subset_2M.sra_1.fastq.gz \  
-2 fastq/SRR7657883.subset_2M.sra_2.fastq.gz \  
--writeMappings salmon_output/SRR7657883/SRR7657883.salmon.sam \  
-o salmon_output/SRR7657883
```

Exercise 3

1. Transform your aligned SAM file in to a BAM file called `SRR7657883.salmon.bam`. Use the option `-@ 7` to use 7 cores. This vastly speeds up the compression.

```
samtools view -b -@ 7 salmon_output/SRR7657883/SRR7657883.salmon.sam \  
> salmon_output/SRR7657883/SRR7657883.salmon.bam
```

⇒ *salmon_output/SRR7657883/SRR7657883.salmon.bam*
